TRENDS ON STAGE IN 2026

THE ARTIST'S PARADOX

While industry treats AI as tool, artists treat it as other and chart new unknowns.

Most people think of AI as a productivity tool. Something to work faster, automate tasks, be more efficient. But what if that's not the most interesting thing about it?

Artists are exploring a different possibility: that AI might be something genuinely other. Not just sophisticated autocomplete, but an intelligence fundamentally alien to human cognition. While much of the industry shies away from this idea, artists are leaning into it.

One approach treats AI as "like hiring an alien in your writer's room." That shift unlocks outputs neither human nor AI could create alone.

But, as these systems become increasingly autonomous and execute independently, the stakes sharpen: the more artists push AI's creative potential, the less control they retain over craft execution. Stand still, and the machine absorbs their work and makes it its own.

Artists are mapping this terrain because exploring uncharted territory is what they do. Stasis isn't an option. They'll need to keep pushing boundaries. What happens when staying creative has never mattered more?

TECTONIC SHIFTS IN IP

Legacy media pivots from protecting content to positioning it as foundational infrastructure for AI generation.

Major media companies spent 2024 suing AI platforms for copyright infringement. By late 2025, they were signing licensing deals and taking equity stakes in the same companies.

Music catalogs, character franchises, and brand archives become valuable not just as content to stream or watch, but as training data that enables AI to create in those styles. Intellectual property shifts from defensive to infrastructural.

The tables appear to be turning. Where IP owners were initially extracted from, they're now positioning to capture value through licensing deals, walled-garden platforms, and equity stakes. And this does not just apply to the entertainment giants; new offerings enable any company with a catalog - the long tail of brands with IP - to build custom generative models from their catalogs.

But the economics remain to be seen. Will IP owners collect meaningful licensing revenue, or simply delay being replaced by AI-generated alternatives? The bet: catalogs transform from static libraries into essential infrastructure in the IP stack.

WORLD MODELS - INTO THE SPATIAL FRONTIER

Language models have hit a ceiling. Spatial intelligence is the next frontier.

LLMs describe worlds they cannot inhabit. World models, by contrast, are rooted in the perception-action loop – the ability to sense space and move through it. They generate consistent 3D environments that "know" what exists behind or beneath an object. This is AI as a material - a computational clay for shaping reality.

The immediate promise is entertainment: we can now build explorable worlds without massive budgets, triggering embodied memory in ways 2D media never could. But the real prize isn't games - it's robots.

This medium relies on a hidden exchange: world models learn spatial logic from human creative play. Every environment we refine provides the grounding signals, the high-fidelity training data needed to enable the next era of intelligent machines and autonomous agents, preparing robotics to navigate our world.

As we use this material to expand our own storytelling, we are simultaneously finishing the machine's education.
